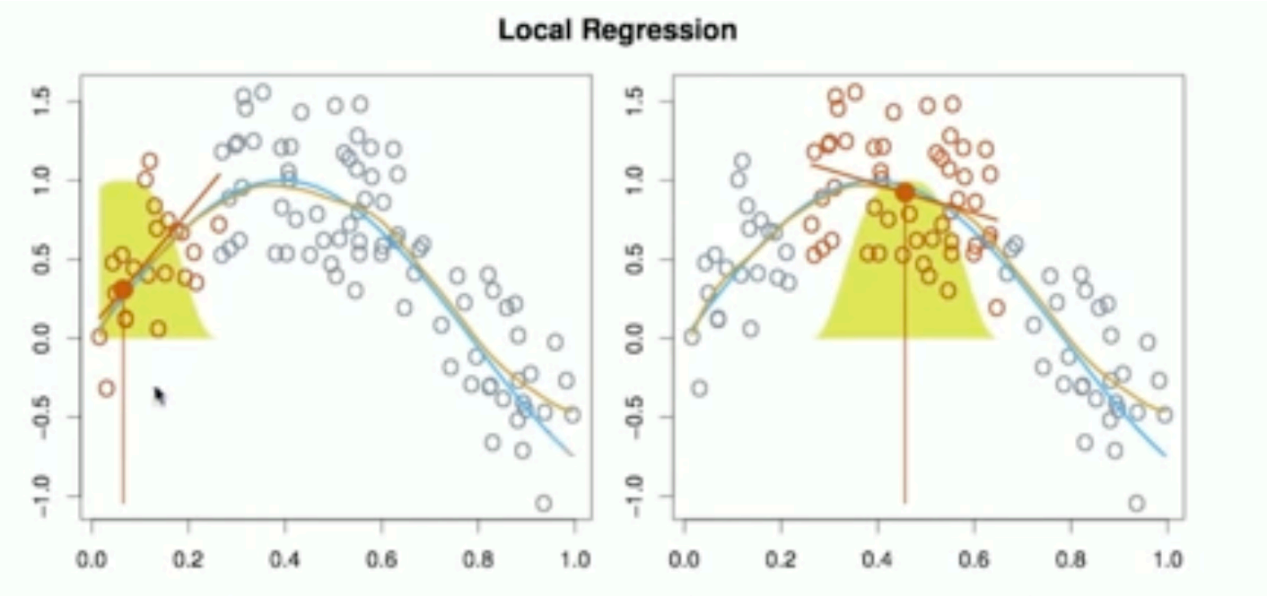
Local Regression


- **Idea**: At each point x_0 where we want to predict, fit a **local** weighted regression using only nearby points.
- Weights are higher for points close to x_0 and decay (e.g., tricube kernel).
- Usually fit low-degree polynomial (linear or quadratic) locally.
- **Result**: smooth curve that follows local patterns closely.
- Very flexible, no global assumption, good for visualization (like in scatterplot smoothing).
